Assessing policy impacts on deadwood in European forests

www.efi.int

Introduction

■ Objective:

- to develop an approach to include deadwood as an indicator for forest biodiversity in the European Forest Information SCENario model (EFISCEN)
- analyse impacts of bio-energy production from forest biomass on deadwood quantity and quality in European forests

Methods

- Definition of deadwood in EFISCEN
 - Standing and lying stems or stem parts that remain in the forest to decompose
- Sources of deadwood in EFISCEN
 - Tree mortality ('natural' death, insects, wind, etc.)
 - Snags
 - Logs
 - Forest management
 - Residues

EFISCEN modelling framework

Methods

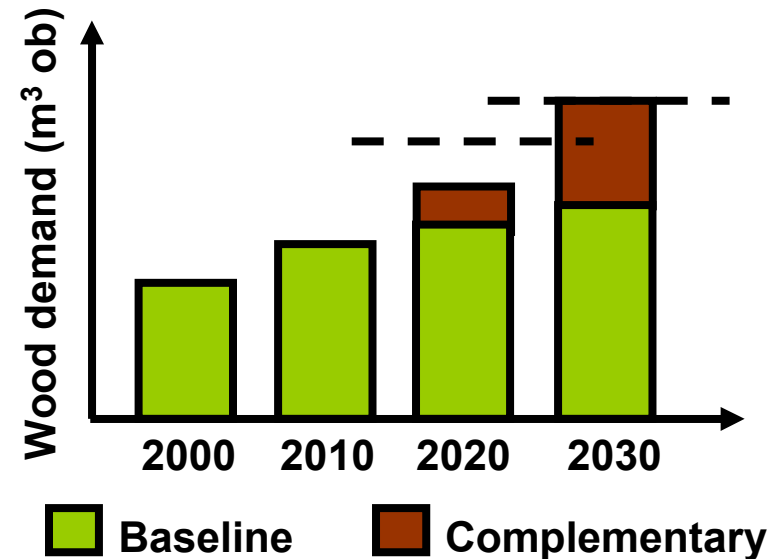

- Add mortality rates and convert net increment to gross increment
 - National forest inventory data
 - Forest inventory websites / reports
 - International databases

- Fall rates
 - Data for England, Finland, Norway, Switzerland and European Russia
 - Assumptions for other countries:
 - Conifers: $t_{0.5} = 15$ yrs
 - Hardwood: $t_{0.5} = 10$ yrs
 - Softwood: $t_{0.5} = 7$ yrs
 - No decay of snags
 - Fractionation of snag

Scenarios

- Baseline: historical wood removals until 2000, EFSOS projections thereafter (Kangas and Baudin 2003)
- Bio-energy: residue removal and complementary fellings after 2010 (cf. EEA 2006)

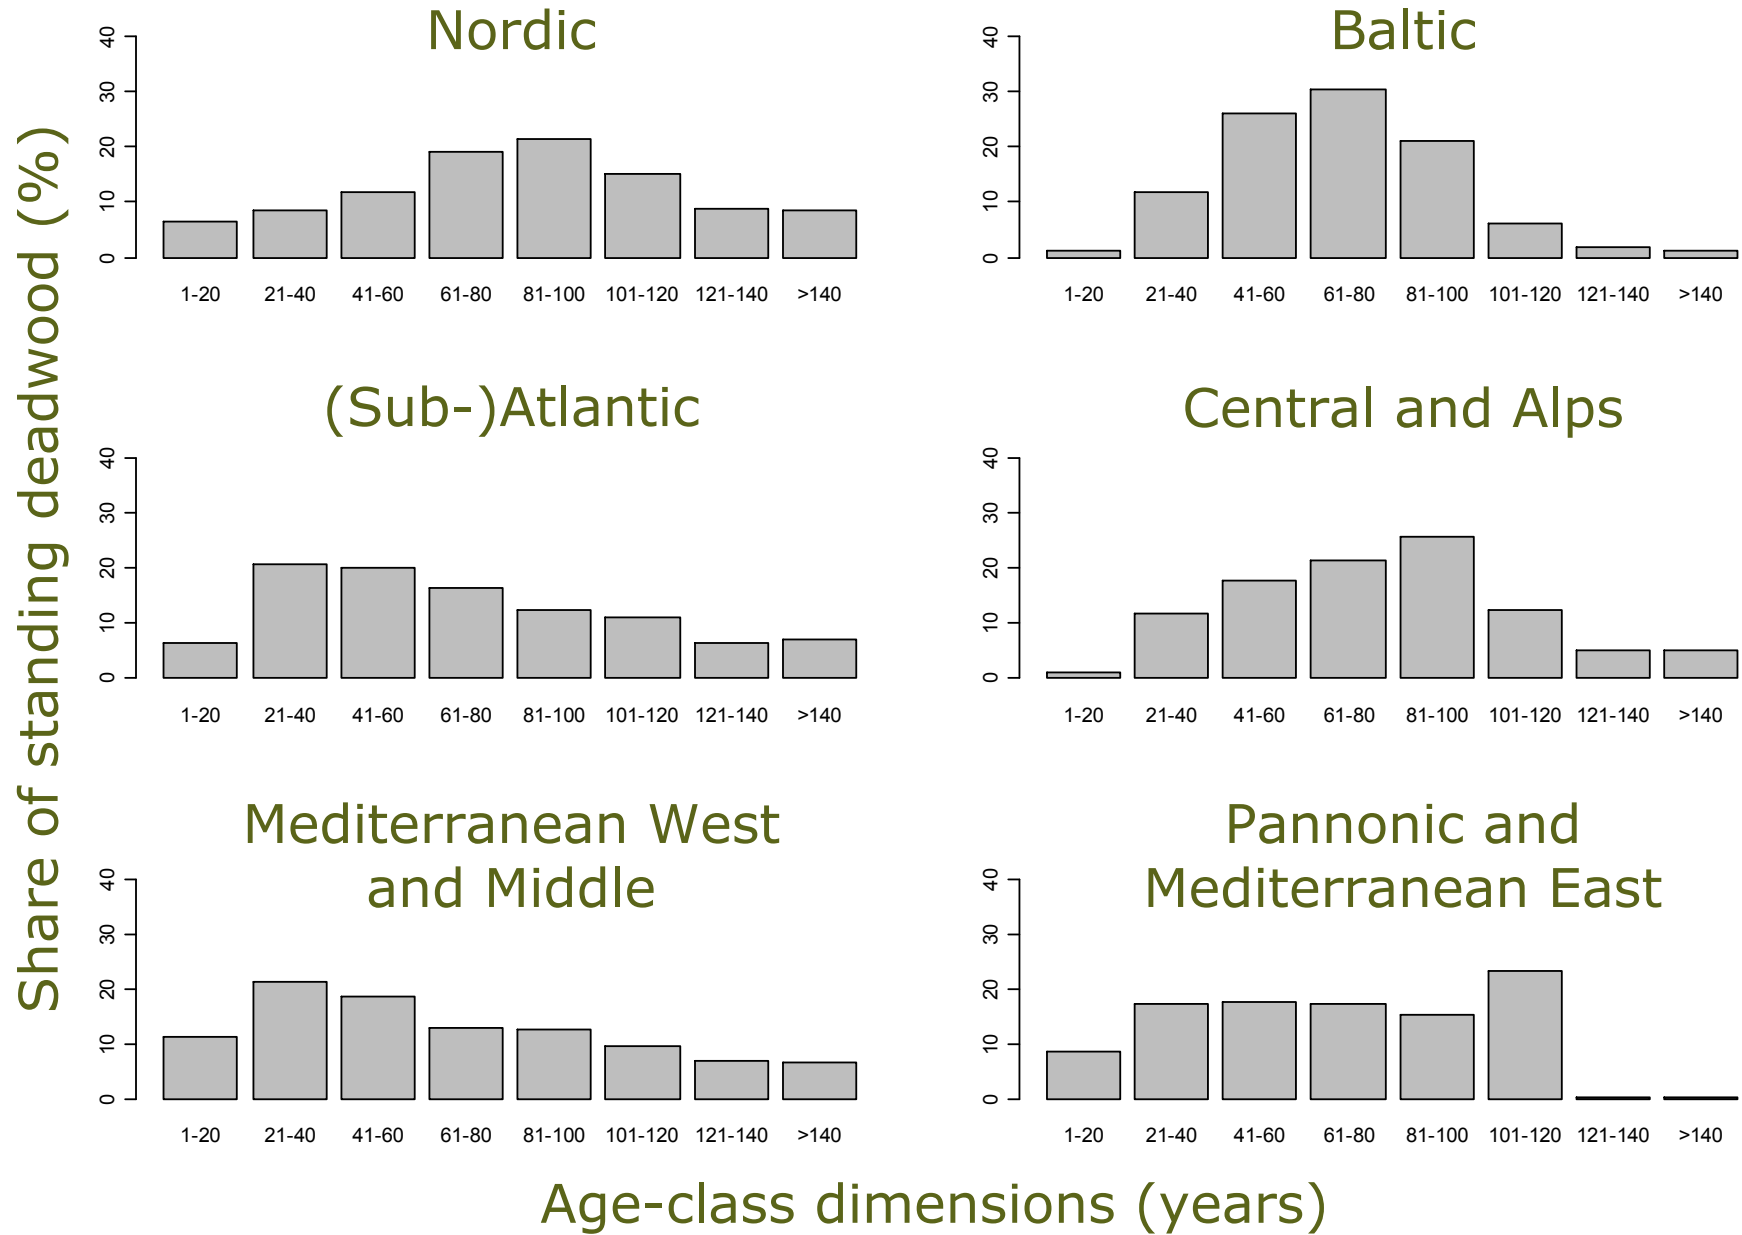

Results: deadwood quantity

Results: deadwood quality

Results: deadwood quality

Share of standing deadwood (%)

Nordic

Baltic

(Sub-)Atlantic

Central and Alps

Mediterranean West and Middle

Pannonic and Mediterranean East

Age-class dimensions (years)

Results: sensitivity analysis

Deadwood (ton ha⁻¹)

- Snags
- Logs
- ⋯▽⋯ Residues
- Total

Uncertainties

- Mortality data not available for many countries
- Mortality agent affects fall rate
- No data on current fuelwood collection and forest residue removal
- Destruction of deadwood during management operations (68% destroyed according to Ranius et al. 2003)

Conclusions

- The quantity and quality of deadwood increases under baseline development and current management practices

- Increasing demand for forest biomass reduces the quantity and quality of deadwood in European forests compared to baseline

- Suggestions for forest management:
 - Create and maintain snags and logs during harvest
 - Reduce salvage fellings
 - Leave behind seed trees to die and decompose
 - But: measures reduce potential supply of forest biomass
